It is worth noting that Shiraya et al. (2011) use the static hedging method (cf. Derman et al., 1995 ; Fink, 2003 ) to compute the barrier option prices under the SABR model, which are essentially options with discrete monitored barriers.

Hence, pricing a European call under the SABR model without arbitrage is equivalent to pricing a down-and-out call option with a knock-out boundary at zero. If it is a put option, then (5) 
$$V_p(t, f, a) = E[(K \mathbb{1}_{F \leq T} + 1 \mathbb{1}_{f > T}) | F = f, A = a] + K \cdot E[1 \mathbb{1}_{f \leq T} | F = f, A = a].$$

The project investigates the prices of barrier options from the constant underlying volatility in the Black-Scholes model to stochastic volatility model in SABR framework. The constant volatility assumption in derivative pricing is not able to capture the dynamics of volatility.
