An OSRAM SFH213 photodiode was selected for this design. In this design the photodiode is minimally reverse biased and therefore the junction capacitance when  $V_R = 0V$  will be used for stability calculations. Also, because of the minimal reverse bias, the effects of dark current on the amplifier output can be neglected.

The Transimpedance Amplifier (TIA) is a useful circuit that allows the circuit-designer to turn light hitting a photodiode into an output voltage. With this circuit in your toolbox, you will be significantly closer to being able to design more advanced circuits such as servomechanisms.

The Transimpedance Amplifier Circuit : 4 Steps - Instructables  
The detailed photodiode-op-amp circuit above including the effect of the photodiode series resistance  $R_s$  can be easily analyzed by recognizing that the input network (to the inverting op-amp terminal) can be simplified using a Norton equivalent circuit with the entire input network replaced by an effective Norton current source  $I_{p_n}$  (which will depend on frequency) and a single Thevenin shunting impedance  $Z_{i_{ef}}$  at the inverting input. With this circuit reduction, the transfer function (to ...

Photodiode/Phototransistor Application Circuit  
This circuit operates the photodiode in photovoltaic mode, where the op amp keeps the voltage across the photodiode at 0 V. This is the most common configuration for precision applications. The photodiode's voltage vs. current curve is very similar to that of a regular diode, with the exception that the entire curve will shift up or down as the light level changes.
